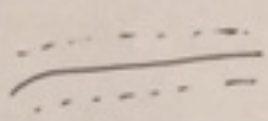
Part I

- Increase over time
- difference become smaller
- uncertainties largest relatively at beginning times
  largest absolutely at end. (2000s)
-

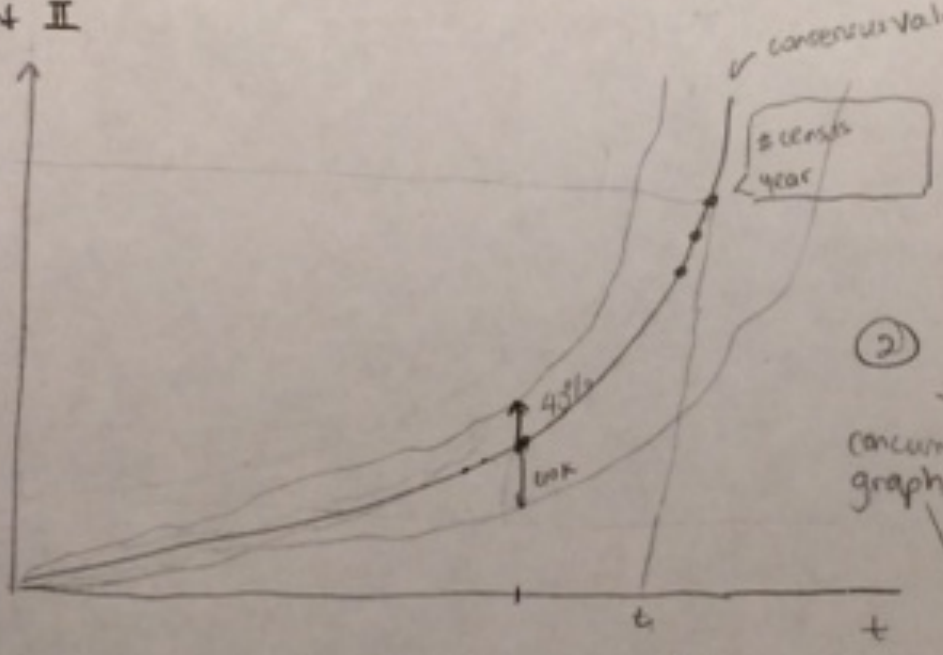


Yes → use log scale to handle large number

→ plot mean and error using different data sets

- Since graph is convex, linear interpolation will give estimates higher than actual data
- Not for the time periods 1600-2000 when the curve is about convex. linear would fit well for the years before and after.

Part II



○ Relative Divergence

○ Absolute diver
